## EM ALGORITHM

# EM ALGORITHM

---

It is a method used to find the models that depend on some latent variables

Not only used in unsupervised learning but also supervised learning

It works as long as it has some latent variables

# EM ALGORITHM

---

- Problem setting:  
Dataset  $Z = \{X, Y\}$  we only know  $X$   
The complete log-likelihood is  $L(\theta|X, Y)$   
 $\theta$  is the model params we want to know
- E-Step
  - Compute the expected log-likelihood given the observed data and params
- M-Step
  - Compute the params that maximize the log-likelihood

# EM ALGORITHM

- General concept of EM

$$\begin{aligned} \log p(x|\theta) &= \log \sum_y p(x,y|\theta) = \log \sum_y q(y) \frac{p(x,y|\theta)}{q(y)} \\ &\geq \sum_y q(y) \log \left( \frac{p(x,y|\theta)}{q(y)} \right) \\ &\geq \sum_y q(y) \log \left( \frac{p(y|x,\theta)}{q(y)} p(x|\theta) \right) \\ &\geq \sum_y q(y) \log \left( \frac{p(y|x,\theta)}{q(y)} \right) + \left( \sum_y q(y) \right) \log p(x|\theta) \\ &\geq \underbrace{\left( -k D(q(y), p(y|x, \theta)) \right)}_{D(q(\cdot), \theta)} + \underbrace{\log p(x|\theta)}_{L(q(\cdot), \theta)} \end{aligned}$$

kL-Divergence

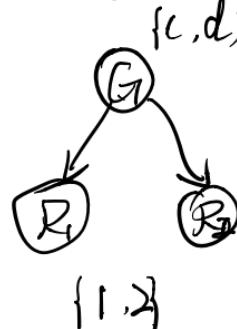

E-Step: Max  $L(q, \theta)$  over  $q$   
 $q(y) = p(y|x, \theta_{old})$

M-Step: Maximize over  $\theta$
